

# Testing Method

The primary and most extensive method of testing utilised was unit testing. Each major feature and their associated methods were tested individually to ensure that within the given inputs the correct outputs were being returned.

Naturally following, integration and system testing was carried out but only to a minimal degree. This was done to a lesser extent due to the continual unit testing carried out prior. By understanding the simplicity of outputs being passed as arguments it is less necessary to thoroughly test upon integration or once feature complete as a system.
